Abstract. In this paper, we provide a survey of certain Communities of Practice (CoP) in the field of formal methods, used for software engineering, especially with respect to state-based notations, using personal knowledge and experience. The multiple communities involved with formal methods are examined here as related CoPs. In this context, the CoPs involved are open communities encouraging participation by al those interested, both in research and application. The authors have both been involved with formal methods over several decades, for most of their careers, and it is hoped that their observations in this paper may help future community building to further the development of formal methods, and software engineering in general. The paper also considers the concepts of Networks of Practice (NoP) and Landscapes of Practice (LoP) in relation to formal methods research and practice, together with a brief introduction to the possibilities of visualizing formal methods CoPs. A bibliography is included at the end of the paper.

1 Introduction

The motivation of this paper is to record experience of developing communities of formal methods researchers with the aim of aiding current and future researchers in successfully growing their own communities around their research interests. Formal methods researchers can be very involved with the specifics and theoretical aspects of their research without considering how it may be used in practice

at some point in the future. This problem continues to this day. In particular, technology transfer issue requires different skills that a researcher may not possess. For ultimate successful deployment, a community with a range of skills and backgrounds is needed, with enough ability and motivation to communicate between each other.

The research methodology in this paper has been to draw on a career lifetime's experience of community building in the field of formal methods to consider how researcher communities are built up over decades. The paper used the social science framework of a *Community of Practice* (CoP), an approach that aids in understanding the evolution of communities that are based around an area of developing knowledge [76,94,95]. The examples provided are intended to help formal methods researchers in considering the state and development of their own communities of fellow researchers and practitioners.

Section 2 gives an overview of the background experience leading to this paper, with some specific community-building examples. Section 3 presents the main results of the paper around the framework of a Community of Practice (CoP) with examples drawn from experience in developing formal methods communities. Section 4 extends the CoP concept to multiple CoPs in a Network of Practice (NoP) and even more widely a Landscape of Practice (LoP), with some examples in the formal methods domain. Section 5 briefly provides an introduction to the possibility of visualizing formal methods CoPs to gain an idea of their nature and structure. Some conclusions on the potential impact of the investigation and ideas for future work are provided in Section 6. The paper includes a substantial bibliography that could itself be used for investigating community structures and interdependence, based on co-author relationships for example.

2 Background

... a job is about a lot more than a paycheck. It's about your dignity. It's about respect. It's about your place in your community.

– Joe Biden

By way of background, the first author of this paper has been involved in building and investigating communities [29], both in the area of formal methods [41], especially the Z notation [47], and also in museum-related [6,57] and arts-related [34,48] contexts. This has been facilitated by the increasing possibility of world-wide virtual communities without geographic bounds [12]. Bowen originally became active in formal methods community building at the Oxford University Computing Laboratory's Programming Research Group (PRG) in the late 1980s. He was a Research Officer working on formal methods [67] and specifically the Z notation [24,62] at the time. He also became involved with the European ES-PRIT **ProCos I** and **II** projects on *Provably Correct Systems*, led by Tony Hoare at Oxford, Dines Bjørner at DTH in Denmark, and others in the early 1990s [7,21,44].

The subsequent **ProCoS-WG** Working Group of 25 partners around Europe existed to organize meetings and workshops in the late 1990s [22]. The

ProCoS-WG final report in 1998 [45] presented comments by members of the group, including those who joined after the start of its formation. For example, Prof. Egon Börger [36] of the University of Pisa in Italy participated at many ProCoS-WG meetings. He was an invited speaker at the ZUM'97 conference [43] and, with Jean-Raymond Abrial and Prof. Hans Langmaack of the University of Kiel, he organized an important set of case studies formalizing a Steam Boiler problem in a variety of formal notations [4], including a number of contributions by ProCoS-WG members. He used ProCoS-WG to present his work on the correctness theorem for a general compilation scheme for compiling Occam programs to Transputer code [17]. The influence of the ProCoS initiative has continued for decades after the original projects and Working Group [32,66].

The BCS-FACS (Formal Aspects of Computing Science) Specialist Group forms another example of a formal methods community in the United Kingdom. Such a community depends on a core committee to keep it active. Although it has been in existence since 1978, there was a period when activities declined in the 1990s. However, from the early 2000s, a new committee was formed, leading to a renewal of activities. For example, in December 2003, the BCS-FACS Workshop Teaching Formal Methods: Practice and Experience was held at Oxford Brookes University [9]. The group also holds regular evening seminars mainly at the BCS London office and selected talks have appeared as chapters in an edited book [11].

In 2008, the newly formed Abstract State Machines, B and Z: First International Conference, ABZ 2008 started in London, UK, edited by Egon Börger (ASM), Michael Butler (B-Method), myself (Z notation), and Paul Boca as a local organizer [15,16]. This was an extension of the earlier ZB conferences, formed from a combination of previously separate B and Z conferences. In 2011, a special issue of selected and extended papers from the ABZ 2008 conference was produced for the Formal Aspects of Computing journal [14]. More recently, a 2018 book on Modeling Companion for Software Practitioners using the ASM approach has appeared [18,33].

3 Communities of Practice

Everything we do is practice for something greater than where we currently are. Practice only makes for improvement.

— Les Brown

A Community of Practice (CoP) [94] is a social science concept for modelling the collaborative activities of professional communities [12] with a common goal over time [95,98]. It can be relevant in a variety of contexts, for example, agile methods [73,99], student teaching in higher education [78,79,80,82], and developing large organizations [87]. Information on the successful creation of a CoP is available [93]. CoPs are typically open communities and it is in this context that they are discussed in this paper.

A CoP modelling approach can be used in various scenarios, for example, in the context of this paper, formal methods communities [30,32,47]. A CoP consists of:

- 1. A **domain** of knowledge and interest. In the case of formal methods, this is the application of mathematical approaches to computer-based specification, modelling and development.
- 2. A community based around this domain. For formal methods, like other academically-based disciplines, this includes conference organizers and programme committee members that are interested in formal methods as core facilitators, conference presenters and delegates as participants, as well as other researchers and practitioners involved with developing and using formal methods.
- 3. The **practice** undertaken by the community in this domain, developing its knowledge, sometimes formalized as a *Body of Knowledge* (BoK) [47] see also Section 4. The formal methods community encourages the transfer of research ideas into practical use [63,64]. Some formal methods approaches have been used in industrial-scale software-based projects, although information on these can be difficult to promulgate due to commercial sensitivities and Non-Disclosure Agreements.

There are various stages in the development of a CoP [94]:

- 1. **Potential:** There needs to be an existing network of people to initiate a CoP. In the case of formal methods as a whole, researchers interested in theoretical computer science, especially discrete mathematics and logic, were the starting point. For example, the initial Z meetings were held with informal proceedings [83,19] in Oxford, due to the location of the Programming Research Group there.
- 2. Coalescing: The community needs to establish a rhythm to ensure its continuation. In the case of many successful formal methods, a regular specialist workshop is typically established initially. For the Z notation, a more formal Z User Meeting (ZUM) was established, together with a Z User Group (ZUG) established in 1992 [46]. Initially, meetings were in the United Kingdom, but it then became an international conference in 1995 [40]. Online information was maintained, initially as a FTP service with an associated Z FORUM electronic mailing list [25].
- 3. Maturing: The community must become more enduring. An initial workshop series may become a more formal conference series and establish itself internationally. With maturity, there may be merging with other formal methods. For example, the International Conference of Z Users became the ZB conference in 2000 [39], combined with the B-Method, and then the ABZ conference, combining ASM, the B-Method, and the Z notation in a single conference in 2008 [15]. This conference has continued through to the present [85]. Another sign of maturity is the production of a standard, e.g., the international ISO/IEC standard for the Z notation [68]. The FTP service became a website and the Z FORUM mailing list was linked with the comp.specification.z newsgroup [25] (now part of Google Groups).
- 4. **Stewardship:** The community needs to respond to its environment and develop appropriately. A particular formal methods community should interact

with related organizations, e.g., those associated with similar formal methods. Overall, Formal Methods Europe (FME, https://www.fmeurope.org) has acted as a stewarding organization internationally, developing beyond the bounds of Europe, and organizing the regular FME conference from 1993 [101], becoming the FM conference more recently, and following on from the original VDM conferences.

5. Legacy: All CoPs eventually end; if successful they morph into further communities. State-based formal methods communities such as those around ASM, B, VDM, Z, etc., have coalesced around the ABZ conference, which continues to this day, as noted above [85]. The various CoPs around these approaches are at different levels of development with respect to their CoP evolution. Currently, as of 2021, there is much activity around the B-Method and the related Event-B. Research around ASM is also still active. However, research on VDM and Z is now somewhat dormant. Exactly how all these related communities will continue is something that is worth considering and planning for at the appropriate time.

It remains to be seen precisely what legacy the various state-based formal methods, especially those associated with the ABZ conference, leave in the future. For the moment, the various communities continue to come together through the ABZ conference, as well as other more informal and individual interactions.

It is interesting to reflect on the occurrence of various formal methods and tools in the titles of papers in the two most recent ABZ conference proceedings for 2020 [86] and 2021 [85], as reported by Bowen [35]. Event-B is the most popular formal method, with 14 papers. 11 papers mention the Rodin tool, providing Event-B tool support. There are nine papers with ASM in the title (including two mentioning the associated ASMETA toolset). Alloy, a Z-like language with tool support, is mentioned in three paper titles, as is the ProB tool providing tool support for B. The Atelier B, UML-B, and UPPAAL tools are each mentioned in one title. TLA, VDM, and Z are not mentioned in any paper titles. So, the "A" (ASM and Alloy) and "B" (mainly Event-B with the associated Rodin and ProB tools) in conference title "ABZ" are still active with respect to research, especially strongly in the cases Event-B/Rodin and ASM. However, the "Z" part of the conference has essentially disappeared. That said, Z is still an inspiration for some formal methods research and is still used in industrial projects, even if not widely publicized. Tools are increasingly important for industrial use of formal methods at scale.

4 Networks and Landscapes of Practice

The idea of a *Community of Practice* (CoP) was originally introduced in 1991 [76]. Since then, the concept has been augmented further, firstly with the notion of a *Network of Practice* (NoP) in 2000 [54] and most recently a *Landscape of Practice* (LoP) in 2014 [97,96].

In a CoP, researchers and practitioners are connected and mutually engaged [84]. An NoP connects several CoPs where there are connections but not neces-

sarily deep mutual engagement. For example, state-based formal methods have connections between them, but they each form separate CoPs.

Some key state-based formal methods CoPs are summarized in Figure 1, together forming an NoP. There have been a number of comparative studies covering various formal methods approaches. For example, a 1996 Steam Boiler Control case study competition book demonstrated different formal methods [4,5]. A 2001 book [56] (second edition in 2006 [59]) presented the questions that should be answered in developing an example invoicing case study using a variety of formal methods. These indicate the connections between these CoPs, but the contributions tend to be submitted independently by members of the relevant CoP. The ABZ conference [86,85] has also be important in cementing ties between state-based formal methods CoPs as previously mentioned, helping to form an NoP. Similarly, FME and its associated FM (formerly FME [101]) conference have also helped significantly in forming a formal methods NoP internationally. On a smaller scale, the BCS-FACS Specialist Group, as mentioned earlier, has helped to play a similar role in the United Kingdom [9,10,11].

Alloy: Daniel Jackson [71].

ASM: (Abstract State Machines) Egon Börger & Yuri Gurevich [13,18].

B-Method & Event-B: Jean-Raymond Abrial [2,3]. TLA: (Temporal Logic of Actions) Leslie Lamport [75].

VDM: (Vienna Development Method) Dines Bjørner & Cliff Jones [72].

Z: Jean-Raymond Abrial & Mike Spivey [1,68,88].

Fig. 1. Some key state-based formal methods CoPs with their major progenitors/promulgators.

Formal methods also overlap with CoPs in other areas that require a rigorous basis to their approaches. For example, formal methods are beneficial for compilers [49,60,61], Hardware Description Languages (HDL) [53,102], Human-Cyber-Physical Systems (HCPS) [77], logic programming [20,23,26], safety-critical systems [27,92], security [51,52], software maintenance [37,38,90], software testing [74,91], etc. That said, there can be some resistance to accepting formal methods in some communities within software engineering as a whole [8,42,65]. Education and training are important aspects with respect to the acceptance and promulgation of formal methods [28,31,55].

An LoP is even wider than an NoP, crossing boundaries and peripheries between CoPs with more widely related interests. Typically this identifies the communities following the same *Body of Knowledge* (BoK), making up the collection of activities, concepts, and terms associated with a professional domain, normally defined by the relevant professional association or learned society. In the case of formal methods, there have been some efforts to define specific BoKs

[47], for example, specifically for model checking in software development [89] and in the railway domain [58].

More widely, formal methods CoPs largely form part of the field of software engineering, although the approach can be applied to computer hardware design as well. Software engineering has a BoK originally developed by the IEEE Computer Society and issued as an ISO/IEC international standard, first in 2005 [69] (187 pages), with an updated version issued in 2015 [70] (336 pages), known as "SWEBOK". The SWEBOK standard covers software requirements, design, testing, etc., all areas where formal methods can be an appropriate approach, especially in safety and security-critical systems.

5 Visualization of Communities

Visualization of CoPs can aid in the identification of knowledge innovation and transfer between CoPs [81]. It is possible to visualize and formalize communities, especially if online [29,48]. In addition, patterns in citations can be investigated formally [50]. Finding co-author and citation relationships can help in understanding the structure of a CoP and its interconnections within an NoP or LoP. In the mathematical LoP, the Erdös number (the distance through co-authorship from the highly collaborative 20th-century mathematician Paul Erdös) is often used as a measure for a particular mathematician's involvement in the mathematical research community [48]. This measure applies to formal methods researchers as well, being one of the more mathematical areas of computer science [29].

There are various visualization tools online that allow graphical views of coauthors and cited authors. As an example, consider the case of a 2009 formal methods survey in the ACM Computing Surveys journal [100], using the online Connected Papers tool (https://www.connectedpapers.com), as illustrated in Figure 2. It is quickly possible to identify clusters of citations by the co-author (top and right of Figure 2). In the righthand cluster, two of the co-authors have collaborated significantly. These two clusters represent two different formal methods CoPs. The size of the circle for a citation indicates the number of citations that it has received (i.e., broadly, its importance) and the darker the colour, the later the date of the citation.

There is much scope for further research on the visualization of formal methods and other CoPs, which could easily fill a whole paper.

6 Conclusion

Education is for improving the lives of others and for leaving your community and world better than you found it.

- Marian Wright Edelman

As discussed in this paper, there are a number of competing state-based formal methods for modelling computer-based systems. The communities associated

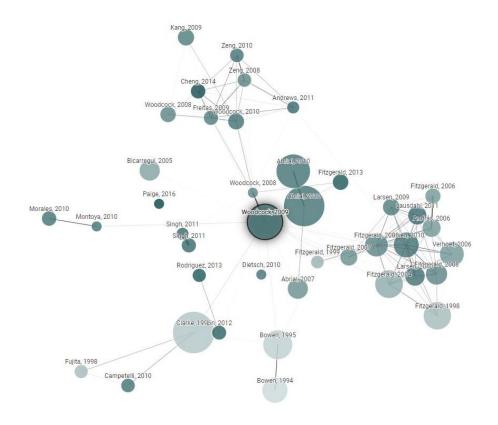

Fig. 2. A visualization of the citations in a 2009 formal methods survey paper [100].

with formal methods have developed since the 1980s, such as the Z notation, the B-Method, Event-B, and ASM. Each approach has its own advantages and disadvantages, which are beyond the scope of this paper to provide in detail. Each also has its own community of adherents, that have now somewhat merged with the establishment of the ABZ conference in 2008 [15]. By their nature, formal methods communities tend to be open communities, with participation by both researchers and practitioners actively encouraged.

The various interrelated formal methods communities may be seen as examples of Communities in Practice (CoP) in action. CoPs can potentially merge and create new CoPs. For example, the B-Method and then Event-B were developed after the Z notation largely by the same progenitor, Jean-Raymond Abrial, with some in the Z community subsequently becoming part of the B community. These interrelated formal methods CoPs form a Network of Practice (NoP).

From experience, a successful Community of Practice depends on people with different skills for success, be it for ideas, vision, organization, etc. Typically, a small number of key personnel are needed for the successful launch of any new

formal methods community. Figure 1 provided some key initial personnel for a selection of state-based formal methods. A successful CoP then needs to reach a critical mass in size, following some of the developments covered in this paper.

The earliest formal methods communities were formed around VDM and Z, which grew up in parallel, although Z concentrated on formal specification at a high level with little tool support, whereas VDM also considered refinement towards program code more explicitly. These are now in the late stages of a CoP. ASM developed separately somewhat later and its flexibility has proved useful on modelling systems at a high level. Due to the lack of refinement and tool support in Z, the B-Method and then Event-B were developed to more explicitly handle these aspects with some compromise on the high-level nature of the language. Alloy also provides tool support using a Z-like language that is useful as a prototyping tool, perhaps for more intricate or critical parts of a large Z specification that could benefit from closer investigation for example. Judging by the activities reported in recent ABZ conferences, Event-B is the most active CoP at the moment. Future formal methods CoPs need to ensure good industrial-strength (and ideally open) tool support for success.

This paper has considered formal methods CoPs, and briefly discussed associated Networks of Practice (NoPs), an overall Landscape of Practice (LoP), and visualization of these communities. Further research could be usefully undertaked in these additional areas. Bibliographies such as the one at the end of this paper and other more substantial databases such as Google Scholar (https://scholar.google.com) could be used for investigating formal methods community structures and interdependences, based on co-author and citation relationships.

Predicting the future is always difficult, but formal methods communities have been successful enough to leave their mark on the computer science community as a whole. Certainly, the most active formal methods CoPs have shifted from consideration of fundamental ideas to tool support, enabling better potential for industrial usage. The experience of the authors is mainly with state-based formal methods, but the examples in this paper may also be applicable to model-checking communities, for example. In any case, the authors hope that the experiences presented here will help future researchers in developing a Community of Practice based on their own research.

Acknowledgements: The authors are grateful to many formal methods colleagues for inspiration and collaboration over the years. Jonathan Bowen thanks Museophile Limited for financial support. The reviewers provided some helpful comments, especially with respect to landscapes of practice.
